**Abstract.** Globular Cluster (GC) formation seems to be a widespread mode of star formation in extreme starbursts triggered by strong interactions and mergers of massive gas-rich galaxies. We use our detailed chemically consistent evolutionary synthesis models for spiral galaxies to predict stellar abundances and abundance ratios of those second generation GCs as a function of their age or formation redshift. Comparison with observed spectra of young star clusters formed recently in an ongoing interaction (NGC 4038/39) and a merger remnant (NGC 7252) are encouraging. Abundances and abundance ratios (and their respective spreads) among young and intermediate cluster populations and among the red peak GCs of elliptical/S0 galaxies with bimodal GC color distributions are predicted to bear a large amount of information about those clusters' formation processes and environment. Not only the bright young clusters but also representative populations of "old" GCs in E/S0 galaxies are readily accessible to MOS on 10m class telescopes.

**Key words.** GC abundances – GC formation in starbursts – GC formation in galaxy mergers

## 1. Introduction

Evolutionary Synthesis (ES) models describe the time evolution of galaxy properties on the basis of average Star Formation Histories (SFH) appropriate for the respective galaxy types. We have developed a combined chemical and spectral ES code that allows for a **chemically consistent** description of galaxies. We use 5 sets of input physics (stellar lifetimes and yields, evolutionary tracks or isochrones, and model atmosphere spectra) for metallicities  $[\text{Fe}/\text{H}] = -1.7, -0.7, -0.4, 0, +0.4$  and account for the increasing metallicity of successive stellar generations by using input physics appropriate for their respective initial

metallicities as given by the gas phase metallicity at their birth. For a standard Salpeter initial mass function the SFHs for Sa, Sb, Sc, Sd models are strongly constrained by average observed colors  $U \dots K$ , template spectra, emission line strengths, and characteristic HII region abundances.

## 2. Star Cluster Formation in Galaxy Mergers

We use the evolution of spiral ISM abundances as presented in Lindner et al. (1999) to predict the metallicities of star clusters forming in spiral-spiral mergers at various evolutionary times or redshifts (cf. Fig. 1).

**Fig. 1.** Redshift evolution of  $[Fe/H]$  for Sa (thick upper line) and Sd (thick lower line) models for ( $H_0 = 50$ ,  $\Omega_0 = 1$ ) from Lindner et al. (1999) (with symbols denoting Damped Lyman Alpha absorber abundances).

### 3. Abundances of Young Globular Clusters

Young globular clusters forming in spiral-spiral mergers will to first order

- form out of ISM pre-enriched in spirals
- with abundance ratios  $[\alpha/Fe] \sim$  solar due to the long timescales for SF in spirals ( $\tau_{SF} \gg 10^9$  yr)

GCs forming relatively late during the extended bursts may eventually

- show additional enrichment during the bursts (typically  $\tau_b \sim 10^8$  yr)
- and abundance ratios  $[\alpha/Fe] > 0$

in fair agreement with young GC spectra in NGC 7252 (Schweizer & Seitzer 1993, Schweizer & Seitzer 1998, Fritze - v. Alvensleben & Burkert 1995).

### 4. Abundances of Intermediate Age Globular Clusters

GCs from the red peak of the often bimodal GC color distributions in E/S0s are good candidates for intermediate age GCs.

- red peak GCs in E/S0 galaxies show  $\langle V - I \rangle \sim 1.2$
- their ages and metallicities bear information about their host galaxy and its violent formation processes

Calculating the color evolution of star clusters of various metallicities (Schulz et al. 2002, Anders & Fritze - v. Alvensleben 2003), we find that GCs with  $\langle V - I \rangle \sim 1.2$  can have a wide range of age-metallicity combinations with very different respective  $V - K$  colors: from  $[Fe/H] = -0.4$  and 13 Gyr with  $V - K = 3.1$  to  $[Fe/H] = +0.4$  and 3 Gyr with  $V - K = 3.6$ . We predict that  $V - K$  data will allow to considerably narrow down the range of age-metallicity combinations. MOS on 8-10 m class telescopes, feasible up to Virgo cluster distances, will soon yield precise abundances and abundance ratios, and hence ages, for these GCs.
